School of Fisheries, Aquaculture and Aquatic Sciences
Auburn University, Alabama 36849 USA

Chlorination Chemicals

Chlorine gas Cl_2

Sodium hypochlorite (bleach) NaOCl

Calcium hypochlorite (HTH) $\text{Ca}(\text{OCl})_2$

Chlorine dioxide ClO_2

Chlorine dioxide usually generated on site from sodium chlorite and hypochlorous acid:

Chlorine Species in Chlorination

Cl₂ = gaseous chlorine

(highly toxic)

HOCl = hypochlorous acid

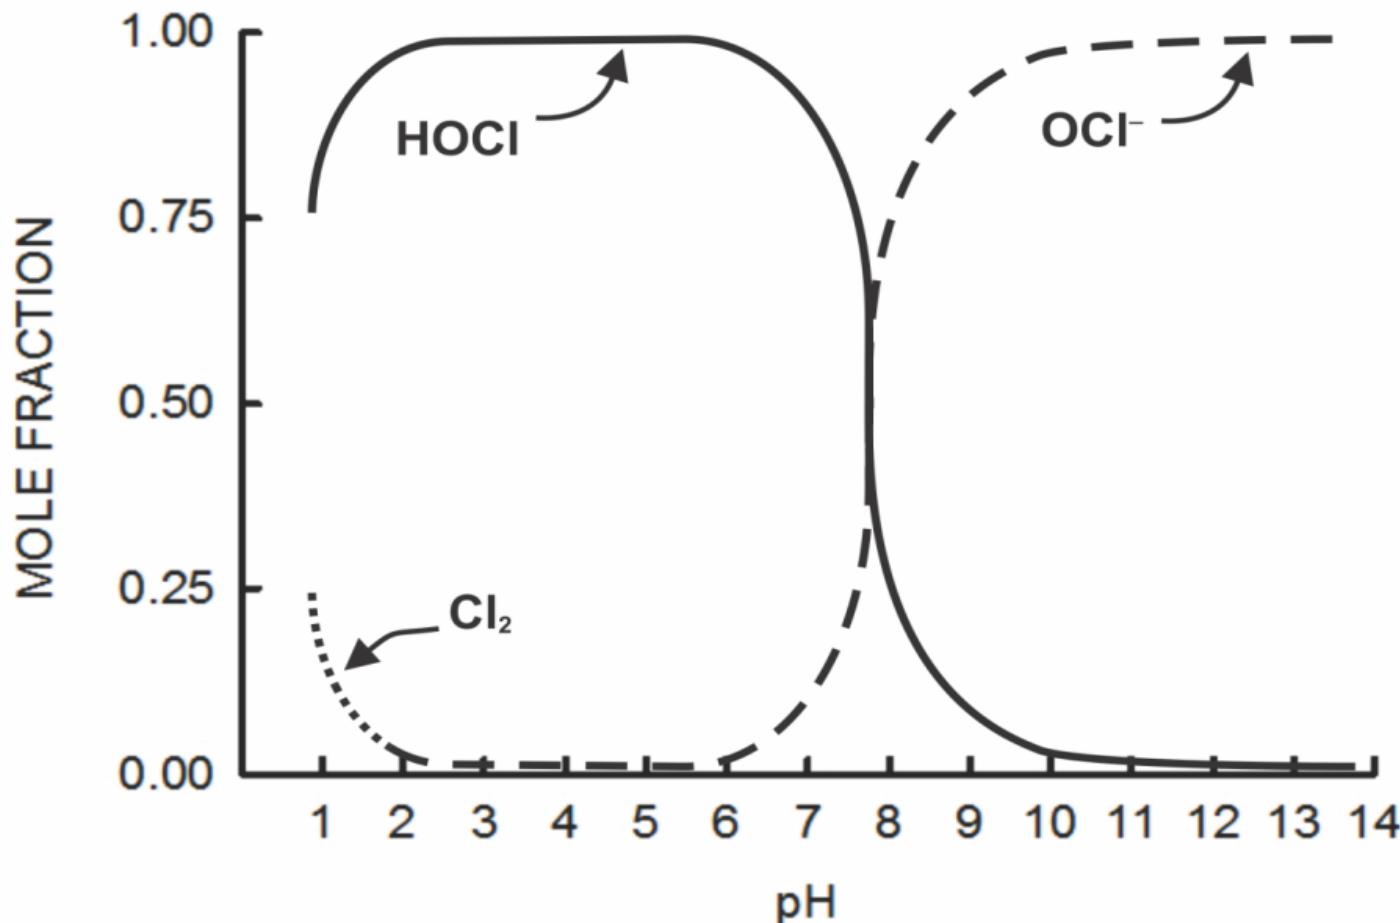

(highly toxic)

OCl⁻ = hypochlorite ion

(less toxic)

Cl⁻ = chloride

(not toxic)

Effect of pH on the concentration of free chloride residuals in water.

Chlorine Demand and Free Chlorine Residual

- Oxidizes reduced inorganic ions (Fe^{2+} , Mn^{2+} , NO^{2-} , H_2S , etc.) and organic matter. In these reactions Cl_2 , HOCl , and OCl^- are reduced to Cl^- .
- Forms chloramines, e.g., $\text{NH}_3 + \text{HOCl} = \text{NH}_2\text{Cl} + \text{H}_2\text{O}$.
- Forms organochlorine compounds with phenol, humic acid, and organic nitrogen compounds.
- Cl_2 , HOCl , and OCl^- remaining after reactions is the free chlorine residual.

Effective Chlorine Dose

- **Chlorine residual = chlorine dose – chlorine demand.**
- **Chlorine dose = desired chlorine residual + chlorine demand.**
- **For drinking water treatment, the goal usually is to obtain a free chlorine residual of 0.2 to 0.5 mg/L.**
- **But, in shrimp hatcheries, a concentration of 1-2 mg/L would likely be better.**

Kill Time

Disinfection (kill) is proportional to disinfectant concentration × exposure time

$$\text{Kill time (min)} = \frac{K}{\text{Free chlorine residual (mg/L)}}.$$

K for free chlorine residuals (>10°C):

<u>pH</u>	<u>K</u>	<u>pH</u>	<u>K</u>
6.5	4	8.0	16
7.0	8	8.5	20
7.5	12	9.0	24

Example: Kill time for 1.1 mg/L residual chlorine at pH 8.0 at which K = 16:

$$\text{Kill time} = \frac{16}{1.1} = 14 \text{ min.}$$

Deactivation of Chlorine Residuals

- Sunlight

- Sodium thiosulfate:

7 mg/L sodium thiosulfate will remove 1 mg/L Cl₂.

Alternative Methods of Water Disinfection

- Ozonation – ozone (O_3), no residues.
- Chloramination – Chloramine (NH_2Cl); longer residual time than chlorination
- Bromination and Iodination – less toxic to pathogens than chlorination.
- Filtration – requires very fine filter.
- UV Radiation – UV is toxic and it also generates ozone.

Ionic Imbalance

- Salinity results almost totally from major ions, but even with acceptable salinity, ionic imbalances may occur.
- Ionic imbalance can result in molting problems, stress, poor growth, and mortality of shrimp.
- The most important concern is the molar ratio of Na^+/K^+ , but the molar ratio $\text{Mg}^{2+}/\text{Ca}^{2+}$ also is important.

Contractions of major ions in normal seawater.

Anions	mg/L	Cations	mg/L
Cl ⁻ (chloride)	19,000	Na ⁺ (sodium)	10,500
SO ₄ ²⁻ (sulfate)	2,700	Mg ²⁺ (magnesium)	1,350
HCO ₃ ⁻ (bicarbonate)	142	Ca ²⁺ (calcium)	400
Br ⁻ (bromide)	65	K ⁺ (potassium)	380

Molar ratios:

$$\text{Na}^+/\text{K}^+ = \frac{10,500 \text{ mg/L} \div 23,000 \text{ mg Na}^+/\text{mole}}{380 \text{ mg/L} \div 39,100 \text{ mg K}^+/\text{mole}} = \frac{0.457}{0.00971} = 47.1.$$

$$\text{Mg}^{2+}/\text{Ca}^{2+} = \frac{1,350 \text{ mg/L} \div 24,310 \text{ mg Mg}^{2+}/\text{mole}}{400 \text{ mg/L} \div 40,080 \text{ mg Ca}^{2+}/\text{mole}} = \frac{0.0555}{0.00998} = 5.56.$$

Potassium and Magnesium Sources

- Muriate of potash fertilizer (KCl); 50% K⁺: 1 mg KCl/L gives 0.5 mg K⁺/L.
- K-Mag® (potassium magnesium sulfate); 17.8% K⁺ and 10.5% Mg²⁺: 1 mg/L K-Mag gives 0.178 mg K⁺/L and 0.105 mg Mg²⁺/L.
- Epsom salt (MgSO₄·7H₂O); 9.86% Mg²⁺: 1 mg/L Epsom salt gives 0.099 mg Mg²⁺/L.
- Magnesium chloride (MgCl₂·6H₂O); 12.0% Mg²⁺: 1 mg/L magnesium chloride gives 0.12 mg Mg²⁺/L.

Potassium Rate to Balance Na⁺/K⁺ Ratio

- Suppose water has 19,000 mg Na⁺/L
 $9 \text{ g Na}^+/\text{L} \div 23 \text{ g/mole} = 0.391 \text{ M}$) and
 $0.2 \text{ g K}^+/\text{L} (0.2 \text{ g /L} \div 39.1 = 0.0051 \text{ M})$
- $\text{Na}^+/\text{K}^+ = 0.391/0.0051 = 76.7.$
- $\text{Na}^+/\text{K}^+ \text{ seawater} = 47.1.$
- $0.391/\text{K}^+ = 47.1; \text{K}^+ = 0.0083 \text{ M.}$
- Increase K⁺ by $0.0083 - 0.0051 \text{ M}$ or by 0.0032 M.
- $0.0032 \text{ mole/L} \times 39.1 \text{ g K}^+/\text{mole} = 0.125 \text{ g/L} = 125 \text{ mg K/L.}$

Ion concentrations in evaporating seawater at different salinities.

Ion	Salinity (mg/L)					
(mg/L)	28,550	56,390	99,410	206,330	302,050	360,150
Cl	15,820	31,240	55,030	116,700	172,600	188,400
SO ₄	2,206	4,367	7,732	13,210	17,290	50,890
Na	8,750	17,310	30,550	64,920	96,070	71,480
Mg	1,056	2,080	3,649	7,744	11,500	36,450
Ca	342	667	1,159	1,017	547	175
K	317	625	1,102	2,337	3,455	10,890
Ratios						
Na/K	46.9	47	47.1	47.2	47.3	11.2
Mg/Ca	5.1	5.1	5.2	12.5	34.5	343.0

Composition (mg/L) for major ions in two commercial ocean water salt mixes as compared to seawater composition.

Ion	Crystal Reef	Instant Ocean	seawater
Cl ⁻	19,778	19,290	19,000
Na	10,114	10,780	10,500
SO ₄	3,324	2,660	2,700
Mg	1,209	1,320	1,350
Ca	380	400	400
K	359	420	380
Br	9	56	65

Quantities of salts diluted to exactly 1.000 L for preparation three selected artificial seawater formulae.

	Salt quantity (g/L)		
Salt	McClendon et al. (1917)	Subow (1931)	Lyman and Fleming (1940)
NaCl	26.726	26.518	23.476
MgCl ₂	2.260	2.447	4.981
MgSO ₄	3.248	3.305	3.917
CaCl ₂	1.153	1.141	1.102
KCl	0.721	0.725	0.664
NaHCO ₃	0.198	0.202	0.192
NaBr	0.058	0.083	0.096
H ₃ BO ₃	0.058	---	0.026
Total	34.441	34.421	34.481

Calcium Carbonate Saturation Index

- $\text{HCO}_3^- \leftrightarrow \text{H}^+ + \text{CO}_3^{2-}$.
- $\text{CO}_3^{2-}:\text{HCO}_3^-$ ratio increases with greater pH.
- When CO_3^{2-} and Ca^{2+} concentrations exceed the solubility of CaCO_3 , CaCO_3 precipitates.
- Online CaCO_3 saturation calculators (best one is Langelier Saturation Index) calculate CaCO_3 saturation pH. Need: total alkalinity; calcium; total dissolved solids (salinity); water temperature; pH.

Calcium Carbonate Encrustation

- Calcium carbonate (CaCO_3) can precipitate from water in hatcheries.
- A deposit of CaCO_3 can develop on shrimp and cause mortality.
- Production in pH by adding acid can avoid this problem.

Carbohydrate Addition in Biofloc Systems

- Ammonia-N is removed from water by bacteria and converted to protein.
- O-C + Ammonia-N → Bacterial-C + CO₂.
- Bacteria have a carbon assimilation efficiency of 5-10%.
- This means that 1 g O-C yields 0.05-0.1 g C in bacteria and 0.90-0.95 g C in CO₂.

Amount of Ammonia-Nitrogen Required in Bacteria Growth

- Bacteria are about 50% O-C and 10% N (dry matter basis).
- Microbial oxidation of 1 g O-C results in 0.1-0.2 g bacterial biomass (e.g., $0.05 \text{ g bacterial-C} \div 0.5 \text{ g C/g bacteria} = 0.1 \text{ g bacteria}$).
- It follows that 0.1-0.2 g bacteria contain 0.01 to 0.02 g N (e.g., $0.1 \text{ g bacteria} \times 0.1 \text{ g N/g bacteria} = 0.01 \text{ N/g}$).

Removal of Ammonia-N by Bacteria

- When a pure carbohydrate (CH_2O) is the source of O-C, ammonia-N is removed from the water for utilization by bacteria oxidizing the CH_2O . From 0.01 to 0.02 g N will be removed for the oxidation of 1 g O-C.
- Utilization of 1 mg/L CH_2O -C by bacteria will result in the release of 0.90-0.95 mg/L CO_2 -C, production of 0.1-0.2 mg/L bacteria, and removal of 0.01-0.02 mg/L ammonia-N.

Ammonia-N Removal by Microbial Utilization of Sugar

- Table sugar or sucrose ($C_{12}H_{22}O_{11}$) contains 42% C.
- To remove 1 mg/L ammonia-N (at 10% carbon assimilation efficiency):
 - $1 \text{ mg/L ammonia-N} \div 0.02 \text{ mg N removed/g O-C utilized} = 50 \text{ mg O-C/L.}$
 - $50 \text{ mg O-C/L} \div (42\% \text{ C in sugar}/100) = 119 \text{ mg sugar/L.}$

Ammonia-N Removal by Black Strap Molasses (BSM)

- BSM is 21% C.
- $50 \text{ mg O-C/L} \div 0.21\% \text{ C in BSM} = 238 \text{ mg BSM/L}$

Potential O-C Equivalent of Feed

- Feed = 35% crude protein (5.60% N); shrimp = 2.75% N; FCR = 1.5.
- 1.5 kg feed = 1.0 kg shrimp
0.084 kg N in feed = 0.0275 kg N in shrimp
Ammonia N = $(0.084 \text{ kg N} - 0.0275 \text{ kg N}) = 0.0565 \text{ kg}$
- 1 kg ammonia-N = 119 kg sugar
 $119 \text{ kg O-C/kg N} \times 0.0565 \text{ kg N} = 6.7 \text{ kg sugar/kg feed.}$
- For BSM = 238 kg O-C/kg N $\times 0.0565 \text{ kg N} = 13.4 \text{ kg BSM/kg feed.}$

Recommendation on Carbohydrate Addition in Biofloc Systems

- Feed has C/N ratio of 7-8.
- Increasing C/N ratio to 12 to 15 will favor bacterial activity.
- Apply 0.5-1 kg CH₂O (sugar) per kilogram of feed added.

Reason that Lower Carbohydrate Rate is Used

- Nitrification – 25 to 50% of ammonia-N is oxidized to nitrate-N by nitrifying bacteria.
- There are some phytoplankton in most floc systems that remove ammonia-N for growth.
- Some ammonia diffuses into the air.
- Some of the organic N in feces and uneaten feed is not oxidized to ammonia-N.

Nitrification

- $\text{NH}_4\text{-N} + 2\text{O}_2 \rightarrow \text{NO}_3^- + 2\text{H}^+ + 2\text{H}_2\text{O}$.
- The reaction requires oxygen and produces acidity (decreases alkalinity and pH).
- For each milligram per liter of ammonia-N oxidized, 4.57 mg/L dissolved oxygen is removed and 7.14 mg/L of alkalinity is neutralized.
- The potential acidity is equivalent to about 0.4 kg CaCO₃/kg feed or about 0.67 kg sodium bicarbonate/kg feed.

Aeration Requirements

- In culture tanks, the oxygen requirement is about 1.1-1.2 kg O₂/kg feed.
- In biofloc systems, O₂ is used to oxidize feed waste as well as added organic matter.
- 1 kg CH₂O (40% C), requires about 1.07 kg O₂/kg CH₂O – roughly the same as feed.
